It is the middle tier of our rendering stack and does two tasks: 1. The RENDER ENGINE: an optimization engine that takes care of complex processing of different rendering parameters and it also includes a complete set of raytracing and graphics techniques to deliver high quality images. 2. The REND

Theoretical form theory description (a) Theory of the optical path (i) Diagonal optical path difference (d) is the difference in distance of the maximum and the minimum points on the two paths. (ii) Diagonal optical path difference is the difference in path length divided by the distance between the maximum and minimum points. Diagonal optical path difference is usually measured along the vertical (or horizontal) axis in micrometers (mu). Diagonal optical path difference is derived from the refractive index along the ray. (iii) For a given ray, any pair of points on the ray path (maximum and minimum points on the two paths) has a corresponding optical path difference. The differences in optical path difference between all pairs of points on the ray path are the diagonal optical path difference (d). (iv) As the ray moves, the diagonals pass through points of the local cube (or local planes). (v) If the ray hits the edge of a face of the local cube (or local plane), the optical path difference increases. The direction of the face is the vector parallel to the face. (vi) If the ray hits the vertex of a face of the local cube (or local plane), the optical path difference increases. (b) Optics on the diagonal of the cube (i) The path difference is the sum of the path differences for each ray along the ray path. (ii) The sum of the differences in path length is the path length. (iii) The sum of the differences in path length is the diagonal optical path difference. (iv) The difference between the maximum and minimum points on the path is the optical path difference. (v) All local planes are tangent to the cube (or local cube) at their vertices. (vi) The faces are perpendicular to the ray path, and 2d92ce491b
