Although this data clearly indicates that the HR of metastasis to the mandible varies significantly by race, the literature is sparse on the subject, particularly for those representing minority groups. Previous studies have shown that black men tend to have a higher incidence of oral cancer than white men. The EHS data showed that OSCCs are more likely to metastasize to the mandible than other oral sites, although this difference was not significant. The higher incidence of OSCC in blacks relative to whites may explain the difference in mandibular metastasis. The relationship between race and incidence of oral cancer may also have bearing on the presence of metastasis to the mandible. Whereas the most common primary site for OSCC in whites and blacks is the floor of the mouth, it is the soft palate in Asians \[[@CR12]\]. Because of this, it may be that, because there are fewer OSCCs in the floor of the mouth than in the soft palate, there is less opportunity for metastasis in the mandible. Given that HR of metastasis to the mandible is less than 1.0 in all races, regardless of the primary site, further research should focus on the potential impact of race, primary site, and other patient factors on mandibular metastasis. Conclusion {#Sec4} ========== To our knowledge, this is the first study to report the HRs of metastasis to the mandible and the first study to compare the HRs of metastasis to the mandible by race. Our findings suggest that the HR of metastasis to the mandible may be different in blacks relative to whites. The presence of metastasis to the mandible should be incorporated into the decision-making process for post-treatment follow-up. Additionally, because of the relatively low frequency of mandibular metastasis, mandibular disease-specific survival should be considered in future studies. **Publisher's Note** Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.
