KEYMACRO - the CSVMerge Torrent Download Tool enables the user to perform two operations on CSV files: 1. Join CSV files together to form a new file. 2. Split a file into multiple CSV files by any specified character string. By default, this tool will not open or write the file after a merge. You can specify the name of the destination file in the InFile, OutFile or InOutFile arguments and specify the name of the source file in the InFile or InOutFile arguments. If you are replacing the contents of the InFile, you must use the InOutFile argument instead. Specify the path to the input file in the InFile argument. Specify the path to the output file in the OutFile or InOutFile argument. All arguments except InFile, OutFile and InOutFile may be either files or the names of the files. Examples: - if the input file (source.csv) is on the drive F:\ and the output file (destination.csv) is on drive D:\, then: \set InFile F:\source.csv \set OutFile D:\destination.csv - if the input file is on drive D:\ and the output file is on drive F:\, then: \set InFile D:\source.csv \set OutFile F:\destination.csv If you use the InOutFile argument, then the destination file is left unchanged and the source file is written to the destination file. NOTE: It is generally best to use the InOutFile argument when splitting large files or files with a large number of records. See the help for more details on all possible options. See the help for an example command line. CSVMerge Torrent For PC

A tiny console application that can be used to merge CSV files (separated by line breaks). It reads the given CSV file into memory as a stream, and lets the user select which file to merge by name or type. If a file name or type is given, it reads the files in a folder by that name or type. Otherwise it merges all files into one single file. A CSV file is just a plain-text file with comma or tab as a separator, for example: Field1, Field2, Field3,..., FieldN
