In 2006, SugarBearHippo built one of the coolest roms around. The Obsidian BB2 is based around the popular Galaxy S gaming phone and brings a much needed touch screen. Then he began to build upon it, adding features. Sure, Galaxy S users could install it, but once they had, they had nowhere to go. Not any more. SugarBearHippo has just released his newest version of The Obsidian BB2. Galaxy S users don't need to, as this ROM now runs on...Galaxy Note. The new Galaxy Note 2 is a touch screen phone just like its predecessors and is actually...well, Google's answer to Apple. If you're interested in finding out more about the fun behind this ROM then you can head over to his. Everything else, such as instructions, etc, has been posted by SugarBearHippo on his forums. There's a 3.28GB (828Mb) apk file available below as well. In current medical practice, there are several ways to deliver medications to a patient. For example, some medications are administered orally by mouth. Alternatively, some medications are administered by injection, e.g., subcutaneous injection, intramuscular injection, intravenous injection, or intradermal injection. Still other medications, e.g., some antibiotics, are administered parenterally via a vein or other bodily passage. It is not uncommon for patients to receive multiple injections for their medications, e.g., several doses over several days. Generally, each type of medication delivery method has advantages and disadvantages. For example, oral administration, while simple and inexpensive, may be unsafe for some medications, e.g., some antibiotics, and some patients, e.g., those with swallowing problems, may be at risk of choking on their medication. An injection, by comparison, is less invasive and more effective for many medications. However, some medications are preferably delivered by injection because of their toxicity and/or efficacy. Thus, each method of medication delivery has advantages and disadvantages. In order to administer medication parenterally via a vein, for example, a needle is typically inserted into the vein. The medication is typically delivered to the patient as a bolus, i.e., a measured dose of medication that is injected at one time as a single injection. This approach simplifies administration of a single dose of medication, but may result in a variety of problems, such as a high concentration of medication being delivered over a relatively short period of time, e.g., within a few minutes or seconds, and in an amount that is likely greater than the desired therapeutic dose for a patient. This high concentration may be painful for the patient, and may be toxic to the patient. In order to reduce the pain experienced by the patient, anesthetizing medication, e.g., lidocaine, may be used with the injection. Alternatively, the medication may be delivered into the vein in a continuous flow at a rate that is lower than the therapeutic dose. While this strategy reduces the concentration of medication delivered to the patient, it may provide an opportunity for the patient to experience pain for a prolonged period of time due to the anesthetic medication. Protein drugs, e.g., insulin, are typically administered by injection, but this approach results in a bolus injection that may be painful and insufficient to provide a therapeutic amount of the protein to the patient. For example, U.S. Patent Application Publication No
