The overall goal of this proposal is to gain a better understanding of the biochemical and molecular mechanisms that control appetite, body weight, and energy metabolism in man. Animal studies have shown that short term nutrient ingestion increases feeding and the subsequent degradation of fuels in liver and skeletal muscle, while long term nutrient ingestion decreases these functions. The molecular basis for these effects have been postulated to reside in the effects of fat on protein synthesis in liver and skeletal muscle, the effects of amino acids on insulin production in skeletal muscle, and the effects of amino acids on rates of nutrient oxidation in skeletal muscle. We have recently shown that 24 hours of fasting also decreases rates of muscle proteolysis in humans. We propose to investigate the impact of nutrient ingestion and fasting on these metabolic pathways in human skeletal muscle. In order to investigate the hypothesis that nutrients affect rates of nutrient oxidation in human skeletal muscle we will employ the "18F-labeled palmitate" technique to measure rates of endogenous fatty
