When I have a pool of tasks, which are independent of each other. I want to use a pool instead of a loop to iterate over the pool because I want to keep a limit for each of them and each of the tasks should be terminated when it reaches the limits. To implement this I thought of using a multiprocessing.Pool. My code is as follows : from multiprocessing import Pool N = 10 data = [] # Creating a pool of tasks with Pool(10) as pool : pool.map(function, range(N)) # Executing this function for i in xrange(N): # do something
With the code above, my pool of tasks executes and all of the tasks are executed on the entire data. When I try to create a pool which has a limit, things goes wrong. With the same code and same data, I expected to get the same results as in the code above. I was expecting that the pool of 10 would have a limit of 10 and would not execute the code outside of the limit. I created the following Pool to do that : N = 10 def function(name): print(name) print("Executing function") for i in range(N): # do something with Pool(10) as pool : pool.map(function, range(N)) The output is as follows : Ignoring 10... Executing function Executing function Executing function Executing function Executing function Executing function Executing function Executing function Executing function Executing function I thought that the limitation was to be applied to the pool instead of to the tasks inside. So I expected to get the following output : Executing function Executing function Executing function
